Product Detail:	Chromosome 1 is the largest human chromosome spanning about 260 million base pairs
	and making up 8% of the human genome. There are about 3,000 genes on chromosome
	1, and considering the great number of genes there are also a large number of diseases
	associated with chromosome 1. Notably, the rare aging disease Hutchinson-Gilford
	progeria is associated with the LMNA gene which encodes lamin A. When defective, the
	LMNA gene product can build up in the nucleus and cause characteristic nuclear blebs.
	The mechanism of rapidly enhanced aging is unclear and is a topic of continuing

	exploration. The MUTYH gene is located on chromosome 1 and is partially responsible for familial adenomatous polyposis. Stickler syndrome, Parkinsons, Gaucher disease and Usher syndrome are also associated with chromosome 1. A breakpoint has been identified in 1q which disrupts the DISC1 gene and is linked to schizophrenia. Aberrations in chromosome 1 are found in a variety of cancers including head and neck cancer, malignant melanoma and multiple myeloma. The FAM43B gene product has been provisionally designated FAM43B pending further characterization.
	Similarity: Belongs to the FAM43 family.
